Bo L - Nutrition Guidance

Your Instructions:
Read this document (at least the sections highlighted yellow). Feel free to reach out with any questions/comments/clarifications.

You're not required to track - although it would make things more optimal, your food log looks very solid and I think you can continue not tracking and still make progress. However, if you want to get the most out of it, I think tracking will be the best option. I will leave it up to you whether we jump straight into tracking or just eat in accordance with the following guidelines and perhaps start tracking later if we're running into issues w/ performance or recovery. It does seem as if you're weighing and measuring some of your meals, so I don't think it'd be too much of a moving piece to begin tracking. Just let me know in the chat, and If you want to track, I'll set up your macros.

Guidance

Regardless, I want you to loosely track protein and carbs.

Be sure to hit the following:
3-4 meals/day OR 3/4 meals + pre/post workout shake/snack
40-50G protein/meal (or ~150-170G/day)
60-75G carbs/day (or 250-300G/day - higher end of range on harder training days)

Take note of the following general "intuitive eating"—eating in accordance with your goals, but without tracking— strategies (you're already doing many of these things):

- Prioritize lean protein w/ every feeding (other than immediately pre and intra workout) throughout the day (it's a good idea yo keep a loose tally of protein grams in your head)
- Prioritize quality carb sources (listed in grocery portion), especially on harder/longer training days
- Prioritize mostly whole, minimally processed foods
- Eat an abundance of different fruits and veggies
- Minimize takeout meals and eating out; I'm totally fine w/ 1 takeout and 1 out to dinner night per week, on average. If some weeks are more, and some are less, that's fine, but eating food you didn't prepare always leaves certain variables to chance. When you do eat out/takeout (at least most of the time), do so with the previous 4 bullets in mind.
- Around training, think "be anabolic". This is somewhat trite sounding, but if you think this way, you'll be more likely to fuel your training sufficiently. What's it mean? It means to ensure you're eating plenty of carbs and protein around training (see specific guidelines in "peri-workout" section later in the doc)
- Track your bodyweight - although you don't have weight gain/loss/body comp goals, per se, tracking your AM wake up weight (before you eat/drink anything) at least a few days/week (daily is fine as well) will give you some relatively trustworthy feedback on

whether you're eating enough. It's not foolproof, and small fluctuations are fine, but if you're trending up or down over a few days to a week, an adjustment should be made accordingly.

- Drink ~½ your bodyweight in oz of water/day as a baseline, and another ~24-32oz per hour of sweating (exercise, sauna, spending lots of time outdoors, etc.). If your urine is yellow or completely clear, you're under/overdoing it. If it's right in the middle (straw color), you're at the sweet spot.
- If you're hungry, eat (in accordance with the first 4 guidelines above). You're lean and fit and you eat mostly whole foods, which means your hunger signals are more trustworthy than someone who eats garbage and has excess body fat (true hunger vs. cravings). Don't feel like you need to restrict yourself. When in doubt, eat
- If you feel depleted (usually a carb quantity thing), up the carbs. "Depleted" subjective symptoms include: difficulty getting a pump in the gym, difficulty matching previous week's loads/rep counts, "heavy legs" on runs/rucks, general fatigue throughout the day. Objective symptoms include: sudden drops in body weight—e.g. you're usually ~180 when you wake up, and one morning (usually after a hard training day) you're suddenly 177 - this can also be a hydration thing, but usually it's a combo of too little carbs and possibly insufficient hydration (the two are closely related, as carbs help us hold onto water in the muscles)
- "Calorie comebacks"/ "calorie hail-marys": if you've had a particularly busy day and you have a lot of ground to make up, you can and should try to do it. If you had a weight loss goal, this would be different, but when chasing performance goals, we want to ensure you're not coming up way short. If you have to eat a massive meal or meal+dessert or meal+snack(s) in the evening to hit your cals, do it. But also use it as a learning experience to better prioritize/plan throughout the day. My strategy for this is the following:
  - Have a higher calorie pre-dinner snack like cheese and crackers or something similar
  - Eat bigger dinner servings
  - Double up on your usual post dinner dessert (or add higher calorie things to it like peanut butter, granola, honey, etc).

*If you have to do this, try to ensure you've wrap it up a couple hours pre-bed. If you're super full going to bed, it can be tough to get sufficient quality sleep. If you happen to do it super close to bed time, hitting a 10-15 min walk afterwards (even if it's around your house) will help expedite the digestion process.

Being mindful of these things will go a long way towards ensuring you're eating appropriately to fuel performance and maintain energy throughout the day. Below, I'll cover some specific "sustains and improves" based on your food log.

Traveling tips/eating out 101: since you travel frequently, I would pre-plan or at least get an idea of some of the better places in the area you're traveling. I can't remember if you travel to the same locations every time, but if so, that's a big advantage.

Takeout options that offer rice bowls, make your own type meals, or lean meats + non fried carbs are the best options. E.g. chipotle, chick fil a, some sandwich joints (Jersey Mikes comes to mind), greek food, mediterranean food, some mexican foods, indian food, jason's deli, etc.

For days you plan on eating out, here are some strategies:

Tracking
-If we track in the future, most restaurants calorie/macros on their menu. You can use those to track, but they're not always reliable so I usually suggest you add 10% to the total calories in it. If not, don't stress it - use your best guess OR if it's only occasionally, don't even track it. I think you can easily have one "free day" per week where you don't track diligently and be totally fine.

Protein
- On days you eat out, ensure you hit your protein target for the day at bare minimum

- Protein leveraging: If you're going to a place that has subpar protein options and you don't want to house down a ton of low protein foods, before going to the restaurant, have 30-40 grams of lean protein. This could be from a shake (note that whey is really fast digesting and not as satiating as other proteins), lean meat, greek yogurt, cottage cheese, or a combination of these. This will fill you up a bit before you go and you'll probably end up eating a bit less than you otherwise would've.

-Do a hard training session before you go out to eat. This can help ensure most of the calories you eat go to muscle and replenishing glycogen, rather than being stored as fat - YES, this is somewhat bro-sciency but I think it's worthwhile.

-Eat a little less throughout the day if you know you're going out. This works well for some people, not everyone. But if you know you're inevitably going to end up eating ½ your days worth of calories at dinner, for example, reduce your portions a bit throughout the day.

-Eat a little less the following day. Again, this only works for some people and should be done reasonably. For me, the thing that affects me most when eating out is digestion. I don't feel as good the day after, so I usually give my digestion a break by delaying my first meal a bit (call it fasting, or not - whatever you prefer), not to "offset calories" but just to allow my gut to recover a bit

Overall, if you're eating out a couple times per week at a place with food that isn't 100% supportive of your goals, no sweat!

If you can choose healthier options that serve similar foods to what you eat anyway (lean proteins, quality carb sources, etc.) you'll feel better and it'll be easier to monitor your total calorie intake.

Sustains x3

Food Selection - your food selection is stellar, no need to adjust anything in the realm of food selection. I would absolutely consider eating some more fruit (see list below for best options), but overall, no big changes needed.

Macro breakdown (per meal) - your meals all have a good protein source and a good carb source, and sufficient amount of quality fat.

Meal count/frequency - I typically recommend 3 meals and 1-2 snacks (pre/post workout or post dinner "dessert"), or 4 meals and a snack. Looks like you're hitting ~3 + a snack or shake, which is excellent. See "peri workout" info below for tips on how to structure your "non-meal" food intake to get the most out of your training sessions.

Improves x2 - minor things, you're very much dialed in. Just some things to consider

1. More Fruit: I would consider eating 3-4 servings of fruit/day. I saw a couple of clementines on one day, but I like to recommend at least 2 servings per 100lbs of bodyweight. Best options: berries (frozen are fine), tropical fruits, apples, peaches/pears/plums, bananas…any fruit is just fine
2. Only a consideration: If you're used to eating with this much variety, by all means keep at it. Your food looks absolutely delicious. But to make things a bit more consistent, you could consider having some 'go-to' meals where you eat the same things for a few days at a time. See 1-2-3 rule below for more specifics.

Peri workout: I define peri-workout as the time spanning ~90 minutes prior to 60 minutes post workout. The calories consumed as well as the hydration protocol followed during this time are crucial for a performance based trainee.

The 2 main considerations for pre workout fueling are **glycogen** and **glucose**.

Glycogen - stored glucose (sugar) inside the muscle cells (and liver in smaller amounts) that provides fuel for optimal muscular performance during hard training sessions (e.g. intervals, lifting weights, tempo/fartlek work) and/or long training (long ruck, long run). The goal should be to ensure your glycogen is "topped off" when you begin a training session. This happens through sufficient overall (not just pre-workout) carbohydrate consumption.

Glucose - circulating (in blood stream) sugar that provides an immediate fuel source for hard training and helps delay the athlete from tapping into glycogen (glycogen sparing). The other main benefit for ensuring circulating glucose is optimized that it's responsible for fueling the brain and nervous system. Your working muscles and cardiovascular system rely on the brain and nervous system to perform motor skills, and glucose is crucial for this interaction.

Because of this, your overall diet and pre training meal are important (glycogen) - as are your immediate pre workout window and intra workout window. Most people are unaware of this intricacy and therefore don't immediately consider peri-workout fueling, which is a mistake.

Considerations (suggested, not required): Consume a small to medium sized meal 90 minutes to 2 hours prior to training. (samples below). During training (lifting day or lifting followed by higher intensity conditioning), consume ~30 grams of carbs on single session days and ~50-60 grams on double session days (sip throughout the first session leading into second - it doesn't need to be perfect). In my experience, the best form of intra workout carbs is vitargo, but gatorade and other carb supplements (the main ingredient you're looking for is dextrose/cluster dextrin/cyclic dextrin) are fine as well. Add electrolytes in the form of salt or an electrolyte supplement and sip throughout training. You can also add a scoop of whey protein (30-40G) if you'd like (just do this on lifting days if you do it, not run/ruck days), but this is less essential than the carbs (carbs are "protein sparing", meaning the presence of carbs in circulation helps prevent muscle loss even in the absence of protein).

If you're training in the morning, liquid calories are totally fine for pre-training. You can slam some fruit juice, gatorade, vitargo, or other supplements. Again, if your total session (start to finish) is less than 75 minutes and you enjoy training fasted, you don't need to consume anything. I would highly suggest hydrating with water + electrolytes, though.

Example peri workout nutrition

Pre workout meal (90-120 minutes prior)
High carb, moderate protein, **low fat, low fiber***
Best Carb sources: rice/rice based cereal, bagel, low fiber fruit, dried fruit or fruit juice, roasted/baked potatoes (boiled potatoes are fine, but very filling - suggest avoiding them in pre workout meal)
Best low/non fat protein sources: lean (95-5 or higher) red meat, chicken breast, greek yogurt, egg whites, whey
Ideal macro breakdown: 35-45 G protein, >10g fat, 60-120g carbs *>5g fiber

Sample meal:
bowl of greek yogurt mixed w/ whey protein, ½ chopped up banana, honey
Large Bowl of rice krispies w/ skim milk

Note: timing is different for everyone - some people like to eat pre workout meals well before training (3-4 hours). This is fine, but the calorie/macro intake should be increased if you're doing this. It's also OK to add a bit more fiber and fat to this meal.

Pre-workout (if session is expected to last longer than 75 min or if it's highly glycolytic - e.g. time trial, speed work)
10-15 minutes prior (25-40g/carbs)
Solids:Gu packet/chews

Liquids: tailwind/vitargo

Intra workout (conditioning session): (if session is expected to last longer than 75 min - e/g your weekend long rucks/runs)
Every 30-45 minutes, consume **as many grams of carbs as possible without GI distress**. This is highly individual and *requires experimentation*. Ensure these carbs are fast digesting, and ideally a mix of different types of sugars.
Best sugar sources: sucrose (combination of fructose/glucose), vitargo, dextrose, maltodextrin
Worst sugar sources: (peri-workout): fructose (without glucose - e.g. fruit)
Starting point: 40-60 grams of carbs per hour (usually about 1.5-2 gu packets). If this feels good, you can add another 10-20 grams of carbs at a time. Slowly increasing in smaller amounts will hopefully help you avoid more serious forms of GI distress. Although our goal is to see where our limit is, we don't want to have to stop a workout or experience "catastrophic bathroom emergencies without the bathroom". If you feel any form of GI distress (gas, bloating, the need to use the restroom, nausea/vomiting), you've likely reached your upper limit. This is key data to have. Now you know where your ceiling is. This ceiling can be raised over time - many high level endurance athletes are able to consume well over 100G carbs/hr. But this takes time and practice - probably not worth messing with in your selection prep. I suggest just taking note of where your hourly intake capped off and sticking just below it.
Hydration: you'll want to consider intra workout water and electrolyte consumption. Depending on the person/weather/sweat rate, 24-32 oz of water and 500-1000 mg of sodium per hour is a good target to shoot for. To get really specific with this, see "Galpin Equation" at the end of the guide in the "resources section".

Solids: Gu packet/chews
Liquids: tailwind (includes electrolytes)/vitargo (add your own electrolytes), watered down gatorade (⅓ water, ⅔ gatorade, and added salt to hit sodium requirements)

Post workout - your post workout meal should very closely resemble (or be the exact same as) your pre-workout meal. If you're done training for the day, your post workout meal can be eaten a bit further from the end of your training session. If you're training again later in the day (e.g. monday's splitting up monday's sessions), you'll want to prioritize getting this meal in sooner, sometime within an hour of finishing. Away from training, it's a good idea to add more fiber and fat to your meals since we've kept them low around training.

Nutrition 101

The following is a rudimentary breakdown on some of the key aspects of nutrition. You do not need to implement the meal prep strategies below - you can stick to what was mentioned above in your 2nd "improve". But you can use it for future reference if desired. Feel free to refer back to this document whenever necessary. *It's not meant to insult your intelligence* - I just like to provide my clients with the basics to do as they please with.

The 3 most important concepts of nutrition are your calories, macronutrients, and micronutrients. Don't think of these as a hierarchy, think of them as all equally important. Here's a simple breakdown of how to conceptualize each one.

Calories

Calories are key for bodyweight management. **The number of calories you consume compared to the number of calories you burn will determine whether you gain, lose, or stay the same weight.** The macronutrients in your food make up calories -

1 gram of **fat** = 9 calories
1 gram of **protein** = 4 calories (although a recent study showed protein to be closer to 3.2 cal/gram - interesting, but semantics for our situation)
1 gram of **carbohydrates** = 4 calories

The *law of thermodynamics* states that energy cannot be created or destroyed - therefore, you cannot gain weight unless you're consuming more calories than you expend. The human metabolism is one of the most complex systems in existence, and it's practically impossible to determine the exact number of calories you're burning or consuming on a given day. You can be significantly more accurate with tracking calories in than calories out. The term for your total "calories out" is your Total Daily Energy Expenditure (TDEE). The sum of the following components equates to your TDEE

- *Basal Metabolic Rate (BMR):* The total number of calories required for bodily functions (organ function, respiration, etc.)
- *Thermic Effect of Food (TEF):* The number of calories required to digest and assimilate the food you're eating. Protein has the highest thermic effect at 20-30%. So for 100 calories worth of protein, you're using 20 to 30 of them just to digest/assimilate these calories, netting a 70-80 calorie total intake (fat has a minimal TEF, carbs 5-10%)
- *Non exercise activity thermogenesis (NEAT):* the number of calories you burn as a result of subconscious movement (scratching your face, fidgeting, tapping your feet, etc.). The range of NEAT between individuals is drastic - ranging from just 200 calories/day to a whopping 1000+
- *Exercise Activity Thermogenesis (EAT):* the number of calories burned as a result of intentional exercise. This is often grossly overestimated by the average person, and is only responsible for 5-10% of your daily expenditure unless you're training several hours/day

The key takeaway from calories is that they determine your body weight - macronutrients and micronutrients serve other key functions.

Macronutrients

Macronutrients (macros) are carbs, proteins and fats (and in some sense, alcohol, which I'll talk about later). Your macronutrient consumption will **determine what you look like** at a given

bodyweight (body composition). If you consume 3,000 calories worth of processed food w/ little protein, for example, you'll look significantly different than you would eating a balanced macro ratio with plenty of protein.

Carbohydrates- Carbs are what provides your muscles with glycogen, which is the preferred fuel source for high intensity training (gym and conditioning). Although carbs are not essential for human life, they're highly important for performance athletes. Although some people feel great on low carbs, these people tend to be rather sedentary - training/preparing for selection and low carb diets do not coexist very well. Not all carb sources are created equal - some are more optimal than others. See grocery list below for the best options.

Protein - protein is an essential macronutrient for human life - a diet void of protein will eventually result in death. The RDA of protein is astonishingly low, and I ensure my clients consume significantly more than that. Regardless of goal, your protein intake will be within striking distance of your bodyweight. Protein is not only important for muscle building and recovery, but it's also the most satiating macronutrient. This is why if you're looking to lose body fat, protein must be high, not just to ensure you preserve muscle, but also to stave off hunger. Conversely, if you're looking to gain weight, protein must be tracked as well. Many people think more protein = more muscle, and past a certain point (.8g/lb/lean body mass) this is not the case. Eating too much protein in a bulk can make getting sufficient calories a chore. But overall, the vast majority of people who think they eat plenty of protein, do not in fact eat plenty of protein. Expect to prioritize this macro throughout your time working with me. See grocery list below for best protein options.

Fat - fat is another essential macronutrient, but despite popular belief, it's NOT difficult to eat sufficient fat. It's actually very easy to go overboard with fat, which is why I believe that most people could easily lose weight if they were more mindful of their fat intake and protein intake. Healthy fat is key for a multitude of functions in the body, to include energy, brain health, temperature regulation, skin, joint health, and hormone health. The minimum required fat intake I prescribe is .3G lbs for men and .4g/lbs for women. Some people do prefer eating higher fat and lower carb, but these are the exceptions, not the rule.

Micros

Micronutrients are the most overlooked of the 3 aspects of nutrition, especially for performance minded individuals. **Micronutrients will determine how you feel** at the bodyweight you're at because of calories, and the body composition you possess due to macros. A micronutrient dense diet will ensure you're internally healthy, able to digest and assimilate foods properly, and allow for overall vitality and well being. The 2 biggest mistakes I see are ignoring micronutrients altogether (eating a diet of mostly processed foods to hit desired macro and calorie intake - aka IIFYM) or not enough food diversity (eating the exact same things all the time with zero variety). As you'll see later, eating consistent foods at consistent times is great, but it shouldn't always be exactly the same. Micronutrient deficiencies should be tested through comprehensive labs at least 1x per year. Efforts should be made to solve deficiencies through food, but supplements are also an option.

Hierarchy

In the hierarchy of what's most important in regards to your nutrition, I want you to keep the following in mind.

Most important

Total Calorie intake - when training for performance, you must be consuming the appropriate number of calories. Even if you're eating 400 grams of carbs per day but you're still in a calorie deficit, your performance will suffer. The main goal each day should be to hit your calories first and foremost.

2nd most important

Protein - Protein is 2nd in line. Without sufficient protein, it's impossible to recover adequately from your training sessions. Protein's biggest benefits for a selection prep candidate boil down to recovery and repair. In most cases, your main goal for the last few months leading into selection are not to gain as much strength and muscle as possible - but that doesn't mean you should disregard protein. Protein consumption will ensure you're recovering from and adapting to the training stressors you put on your body through a process called muscle protein synthesis (MPS). MPS is not only stimulated through consumption of protein, but also through sound strength training. MPS is closely related to recovery, repair, and the addition of lean tissue (muscle). Most studies show that a minimum of 30 grams of protein in one feeding is necessary to reap full benefits of MPS.

Other important things
Micronutrients/food quality
Other macros (fat/carbs)
Timing (for serious physique or performance benefit goals)

Staple Foods (meal prep)

Everyone is different, but I have easy staple foods that I always meal prep because they're versatile and nutrient dense, and easy to make in bulk

White rice
Potatoes
Hard boiled eggs (or any way you prefer eggs)
Ground beef/bison/elk
Chicken thighs or breast
Stir fry vegetables

Strategies (meal prep)

All failed nutrition approaches have one big common denominator - lack of preparation. If you're eating reactively, you'll be inconsistent, more stressed, and more likely to make poor in the

moment decisions. Decision fatigue is real, and if you're deciding what to eat when it's time to eat, you've missed the boat. Instead, follow my **"2 decision meal prep plan"**

Sunday (or any day that works best)- decision # 1: Decide what you're going to eat for the next 3 days. Purchase required food, and prepare it all at once. Store in the fridge (can pre mix meals or put each component in its own package and mix the day of).

Wednesday night - decision # 2: when making dinner, make enough of it to eat for the rest of the week at lunch. You can also make breakfasts and dinners for the following days if those are problem meals for you. Store the same way as above.
Weekend free meal: I don't expect perfection. You're welcome to go out and eat foods you enjoy on the weekend. If you're lean, you can get away with a lot more than if you're fatter.

Outsourcing meal prep: I personally hate cooking for the week, but I'm also pretty busy and, just like anyone else, make terrible food decisions when I don't have anything prepped/planned. If you fall into this category and have the funds to spare, a meal prep service is a great option. I use Factor Meals, and I firmly believe it's the best option out there (unfortunately no discount code yet). But there are other options as well. There's nothing wrong with outsourcing your meal prep to buy back some time/bandwidth.

1-2-3 rule

The 1-2-3 rule is a great hack, and is as follows:

1= your go-to breakfast that you eat 80% of the time (looks like you already pretty much do this)
2= 2 lunches on rotation 80% of the time
3= 3 dinners on rotation 80% of the time

This doesn't need to be exact/perfect (hence 80% of the time), and the foods don't need to be exactly the same (e.g. you can rotate different veggies/fruits/meats). But something all successful nutrition plans have in common is consistency. Just worth considering.

Overall, a diet consisting of **80-90% whole foods** (food that derives from the ground or an animal) is ideal. No issue with eating off plan/foods not perfectly lined up with your goals 10-20% of the time. Once you've reached a point where we have your metabolism revved up, you can "get away" with less than ideal food choices a lot easier.

Grocery List

Protein- Whole food protein sources are always going to be the best. My top choices are:
-Red meat/ruminant animals - this includes: ground beef (90/10 or better), steak (lean cuts like top sirloin, flank, NY strip), elk, bison

**Red meat (non processed, relatively lean) is the most micronutrient dense meat you can consume (other than organ meats- which we won't get into unless you're interested)
-Chicken (breast/ground are leanest, rotisserie/whole chicken or thighs are also fine)
-Turkey (whole or ground - opt for 93/7 or better)
-Fish (wild caught preferred)
-Eggs (whole and egg whites)
-Cottage cheese (2% or lower)
-Yogurt (greek - minimum 13 grams/protein/serving)
-Milk (if you tolerate dairy well - fairlife is great if not)

Fats (most people get enough fat, but here are the best options)
-Olive oil
-Avocados
-Nuts/nut butters
-Quality cheese
-Seeds
-Fish (oily fish like salmon, trout, mackerel, sardines)
-Coconut oil

Carbs (don't fear carbs - a true "carb" is something that is mostly/all carbs, so not pizza, cookies, muffins, etc. you can eat these things, just in moderation)
-White rice (easier digesting than brown rice)
-Potatoes (all kinds - sweet, white, red etc)
-Sourdough bread (sourdough is far easier to digest than other breads - but other breads are fine too)
-Oatmeal
-Rice based cereal (Rice n' grinds is amazing - ask me about it if interested)
-Pasta
-Fruit (best fruits are berries, tropical fruits, citrus fruits, melon - all fruits are fine though!)
-Vegetables (veggies are technically carbs because it's the only macro, but very low in them) Best veggies are green, leafy veggies, carrots, brussel sprouts, cabbage, beets, asparagus - but all are fine! If too many raw veggies mess with your digestion, steam/boil/cook them and this should do the trick.
*Fruit Juice - pre/intra workout option. Gatorade works as well. Since you're probably going to eventually be struggling to get calories, I highly suggest sipping on some intra workout carbs. Not only will it aid performance, but it'll also allow you to sneak in 60-80g/carbs without really noticing it. More specifics on this in the future.

Other Things To Be Cognizant Of

Alcohol - It doesn't take a rocket scientist to know that alcohol will not help you in any way, shape or form. I suggest avoiding it, primarily for its effect on sleep. If you're tracking alcohol, you can track it as fat or carbs. If you're going to drink, I highly suggest doing so prior to a rest day and keeping it to 2 or fewer. If able, finish drinking at least 3 hours prior to bedtime. You're also knowingly sacrificing sleep and future performance by consuming alcohol.

Caffeine - Caffeine is a performance enhancer, especially when used strategically. The more adapted/tolerant you are to it, the less it enhances performance. I typically recommend no more than 400mg/day, and to ensure you're cutting it out at least 8 hours (preferably 10+) prior to bedtime. The best options are coffee, tea or caffeine in pill form. I suggest strictly limiting energy drink consumption.

Labs - I recommend anyone over the age of 20 to get labs done at least 1x/yr. 2-3 times per year is even better. But you don't know if you're truly healthy or what you could potentially do to become healthier if you don't look under the hood from time to time. If you're interested, let me know and I can provide some recommendations for reputable telehealth clinics.

When not to eat: Try to limit eating before bed. This isn't because it'll make you fat, it's because of its effect on sleep. If your last meal is finished 2-3 hours before bed time, you're allowing enough time to digest the food prior to sleeping. This will lead to better sleep quality

Hydration Mistakes: Many type A individuals drink way too much water. I recommend starting with ½ your bodyweight in OZ and adjusting depending on activity level, environment (heat/humidity), and your sweat rate. W/ ½ your bodyweight as a baseline, another 24-32 oz of water (w/ electrolytes) per hour of sweating is usually a good rule of thumb. *Everything you drink besides alcohol counts towards water.*

Dispersion: You can eat equal sized meals, or front or back load your calories. I personally eat ⅔ of my daily calories for dinner/in the evening because it works best for my lifestyle.
